Chapter 1

Introduction

1.1 What is a Data Structures Course

Data Structures is all about defining the different ways we can organize data.

1.2 Why This Book?

1.2.1 Where Does This Book Fit Into a Computer Science Curriculum

Education in Computer Science is based around three core topics: translating the steps of solving a problem into a language a computer can understand, organizing data for solving problems, and techniques that can be used to solve problems. These courses typically covered in a university's introductory course, data structures course, and algorithms course respectively, although different universities decide exactly what content fits in which course. Of course, there is are lot more concepts in computer science, from operating systems and low level programming, to networks and how computers talk to each other. However, all these concepts rely on the knowledge gained in the core courses of programming, data structures, and algorithms.

This textbook is all about Data Structures, the middle section between learning how to program and the more advanced problem solving concepts we learn in Computer Science. Here, we focus on mastering the different ways to organize data, recognize the internal and performative differences between each structure, and learn to recognize the best (if there is one) for a given situation.

1.2.2 What Are My Base Assumptions about the Reader?

This textbook assumes that the student has taken a programming course that has covered the basics. Namely: data types such as ints, doubles, booleans, and strings; if statements, for and while loops; and object orient programming. The first writeup of the textbook will be done in Java, but I will try to add as much Python into the book as well.

Lists

The first data structure we will be studying is the list. The list is by far the most relatable data structure, as humans deal with lists on a regular basis.

4.1 What is a list?

When you get right down to it, lists are defined by order.

```
public static <E> boolean isPermutation(List<E> listA, List<E>
↪ listB) {

    if(listA.size() != listB.size()) {
        return false;
    }
    for(int i = 0; i < listA.size() ; i++){
        E item = listA.get(i);
        int countA = 0;
        int countB = 0;

        for (E element : listA) {
            if(item.equals(element)){
                countA++;
            }
        }
        for (E element : listB) {
            if(item.equals(element)){
                countB++;
            }
        }
        if(countA != countB) {
            return false;
        }
    }
    return true;
}
```

4.2 ArrayLists

4.2.1 Generics

4.2.2 Building an ArrayList

4.2.3 More Restrictive or Permissive Generics

4.3 LinkedLists

I will be presenting the directions to building a fully functional singly-linked list and doubly-linked list. These directions will differ from the mechanics of how your programming language of choice implements them, but have the same time complexity for their operations. My implementation is constructed with the goal of making the code easy to understand and the decisions that need to be for adding and removing reflect each other. Finally, my code aims to minimize the number of null-pointer exceptions and their ilk a programmer would make.

The full implementations can be found at the end of the Chapter.

4.3.1 Building a Singly LinkedList

We open up our linked list with a class declaration. If our language uses generics, we specify it there. I'll be choosing not to inherit from the built-in list so we can focus solely on our own code and no external distractions.

In Java, our code looks like this.

```
public class LinkedList<E> { }
```

In Python

```
class LinkedList(object):
    pass
```

The Node

We want the Node class to be a private/internal class, so that the Node we write for a singly linked list and doubly linked list won't get mixed up in our coding environments. This also applies for other data structures that will be using nodes.

```
public class LinkedList<E> {
    private static class Node<E>{
        E item;
        Node<E> next;

        public Node(E item){
            this.item = item;
        }
    }
}
```

```
class LinkedList(object):
    class Node(object):
        def __init__(self, item) -> None:
            self.item = item
            self.next = None

    pass
```

In the Node private/internal/inner class (and only there), the `this` or `self` refers to the **node** rather than the list.

Instance Variables and Constructor

```
public class LinkedList<E> {
    private int size;
    private Node<E> head;
    private Node<E> tail;
}
```

Adding

When we add items to a linked list,

When we do any kind of operation on a linked list, we need to think about how instance variables in a linked list will be altered. Fortunately, we only have three instance variables: `size`, `head`, and `tail`. When adding to a linked list, the size will

Getting a Node at a Specific Index

```
class LinkedList(object):

    class Node(object):
        def __init__(self, item) -> None:
            self.item = item
            self.next = None

    def __init__(self):
        self.head = None
        self.tail = None
        self.size = 0

    def __len__(self):
        return self.size

    def add(self, index, item):
        if(index < 0 or index > self.size):
            raise Exception("Invalid add at index " + str(index)
                               + " with item" + str(item) + ".")

        adding = self.Node(item)
        if(self.size == 0):
```

```
        self.head = adding
        self.tail = adding
    elif(index == 0):
        adding.next = self.head
        self.head = adding
    elif(index == self.size):
        self.tail.next = adding
        self.tail = adding
    else:
        before = self.getNode(index - 1)
        adding.next = before.next
        before.next = adding

    self.size += 1

def getNode(self,index):
    current = self.head
    for i in range(index):
        current = current.next
    return current

l = LinkedList()
print(len(l))
```

Queues

A Queue (pronounced by saying the first letter and ignoring all the others) is a data structure which emulates the real world functionality of standing in a line (or queue, for those from Commonwealth nations). In a Queue, items are processed in the order they are inserted into the Queue. So if Alice enters the Queue, followed by Bob, followed by Carla, Alice would be the first to leave the Queue, then Bob, and then Carla.

The use cases for Queues are fairly obvi
